How to Generate QR Codes in Bulk from a CSV

1

Prepare your CSV

One row per QR code. Put the link (or any text) in one column. Add a column for the file name and another for a short caption if you want them.

2

Upload or paste it

Load the .csv file or paste rows directly. Everything runs in your browser — your list of links never leaves your device.

3

Map your columns

Tell the tool which column holds the link, and optionally which columns are the file name and the caption printed under each code.

4

Pick format and size

Choose PNG or SVG, set the size and error-correction level, and adjust the quiet-zone margin. SVG stays razor-sharp for large-format print.

5

Generate and download the ZIP

Generate every code, preview them, then download them all together as a single ZIP — named from your file-name column so they stay organised.
